Algal bloom or foaming is a consequence of nutrient enrichment (N and P) due to untreated sewage (mostly from human and household waste and detergents) and industrial effluents. The phosphorus from several sources reaching water bodies causes pollution leading to algal blooms, frothing, etc. Phosphorus represents both a scarce non-renewable resource and a pollutant for living systems.

The phosphorus from several sources reaching water bodies causes pollution leading to algal blooms, frothing, etc. Phosphorus represents both a scarce non-renewable resource and a pollutant for living systems.

Primary nutrient, such as carbon, nitrogen, phosphorus, etc. contribute to eutrophication. In fresh water ecosystem, primary producers are able to obtain N from the atmosphere and hence phosphorus is the primary agent of eutrophication. Meanwhile, the particles eutrophication. Moreover, elements carbon, also serve as collector for surfactant which nitrogen and phosphorus can generate its weight and stabilize the foam. Surfactants contain slowly by 12, 71 and 500 times, and hence phosphorous is the limiting element in primary producers. Nutrients enrichment often leads to profuse growth of invasive species (water hyacinth, etc.), which forms thick mat hindering the sunlight penetration. In absence of sunlight, photosynthetic activities cease affecting the food chain. Absence of sunlight penetration leads to the decline of primary producers (algae) in the region below the macrophyte mat. Most part of nitrogen available in the sewage and industrial effluents is assimilated by producers, while phosphorous gets trapped in the sediment. During premonsoon with high intensity winds, churning of lake water happens, leading to the release of phosphorous from sediments forming froth.

Foaming is the manifestation of interactions among air bubble, surfactant and hydrophobic particles. The hydrophobic particles congregate at the air-water interface and strengthen the water film between air bubbles. Meanwhile, the particles hydrophobic. The hydrophobic particles congregate at the air-water interface and strengthen the water film between air bubbles. Meanwhile, the particles hydrophobic. Thus, frothing is due to the presence of slowly biodegradable surfactants and hydrophobic surface. The hydrophobic particles congregate at the air-water interface and strengthen the water film between air bubbles. Meanwhile, the particles hydrophobic. Thus, frothing is due to the presence of slowly biodegradable surfactants and hydrophobic surface.
Surfactant could stabilize the foaming and allow foam to accumulate.

**Figure 1:** Collection of water and foam samples from Varthur South (V1) and North (V2) outlets (proliferation of filamentous organisms) and air from the detergents, oil and grease that are used in households or industry. Nonylphenolethoxylate (NPE), an endocrine disruptor and estrogen mimic; phosphates, to sustain biota on the Earth and is a nonrenewable resource. The indiscriminate exploitation and abuse of this resource is threatening the sustenance and its availability for future generations is becoming obscure. There has been a series of events (frequent frothing, etc. in water bodies) and subsequent research have clearly highlighted the linkages of enhanced usage and influx of P with a phenomenal increase in P enrichment in surface and ground waters. Consequence of extensive use of detergents, oil and grease that are used in households or industry.
phosphorus usage in contemporary urban societies is the nutrient enrichment or a bulk of the detergents is the builder material eutrophication of water bodies. Studies across that is often made up of Sodium the globe highlight of nearly 2.4–2.7-fold tripolyphosphate (STPP) that significantly increase in nitrogen and phosphorus driven contributes to P enrichment. The levels of P eutrophication of freshwater and marine enrichment in urban water systems is enormous ecosystems with the current level of ranging from 0.5 to >10 mg/l of labile P. humaninduced stresses. The main sources of Abundant P in these systems have substantially phosphate in aquatic environment, is through contributed to increased biomass productivity household sewage water containing detergents and cleaning preparations, agricultural run-off urban aquatic systems that has resulted in containing fertilizers, as well as, industrial rampant proliferation of aquatic macrophytes effluents from fertilizer, detergent and soap industries. The consumption of synthetic detergents is rapidly increasing with urbanization and most of them contain phosphate as a ,,builder”, which has been increasing phosphate loading in water bodies. The estimated annual consumption of phosphate-containing laundry detergents for the current population in India is about 2.88 million tonnes and the total outflow of P is estimated to be 146 thousand tonnes per year. The environmental consequences necessitate immediate policy interventions for checking eutrophication of water bodies, through reduction in Phosphate based detergents and hence P inputs to surface waters. All the detergent manufacturers need to adhere to minimise the use of P in the manufacture of detergents while the authorities need to restrict with stringent norms. Strict control with the vigilant and environmentally conscious public only could ensure that Indian water bodies remain safe and healthy.During seventies and early eighties, 19th century such instances had brought about an increase in global consensus and the public awareness mostly in the European nations and triggered regulations on P loads from Industry and Urban sources. In India there has been a widespread use of P based detergents that has resulted in contamination of ground and surface waters rendering the water unsuitable for any use. One of the major constituents that form the main solutions for cutting short rapid and high P influx into the system is a) Introduction of non-P based builders in detergents for example Zeolite, that can completely replace Sodium tripolyphosphates (STPP - amounts to ~50% bio-available P in municipal wastewaters) commonly seen in detergents and b) Augmenting the existing wastewater treatment system for nutrient removal and recovery. This requires various measures that aids in framing and implementation of laws to completely replace P based builders to alternative non-P based household laundry detergents. Already the European Commission (EC) has implemented non-P based culture in detergents through the European Union (EU) and recommends appropriate measures to improve the present P enrichment scenario. The two main essential P sources in urban conglomerates are the municipal wastewaters
and to a lesser extent agriculture. In most of the Bangalore’s catchment that has an inadequate treatment facility and treatment is mostly upto tertiary levels. Municipal wastewaters represent the single largest P source in urban municipalities. In case of certain areas where people practice agriculture, horticulture and floriculture, a minute amount of P (synthetic fertilisers) escapes from these landscapes, where top soil erosion and land run off are the crucial means of entry of fertiliser P into the channels and freshwater lakes. It has been estimated that P from detergents contributes to an estimated 65% of P in municipal wastewaters and the rest are from excrements etc. Based on the field sample analyses, the recommendations are a) A ban on production of polyphosphate based detergents in Indian systems which will help in usage of trusted non-P based detergents, that would bring down the P loads contributed from detergents in municipal wastewaters and also significantly reduce P loads from all garment, textile and other industries that uses detergents substantially; b) Nutrient removal and recovery mechanisms to be augmented into the existing treatment systems by the help of phyto-phyco modules.

The study highlights the need for immediate intervention towards the reduction in the amount
of sodium tripolyphosphate (STPP) used in detergent builders and switch to “alternative” non-phosphate based builders, such as Zeolite A; and, improving wastewater treatment taking advantage of constructed wetlands in urban wastewater treatment.

Fire associated with foam: Flammability is the ability of a substance to burn or ignite, causing fire or combustion. Incidences of foam catching fire are due to compounds with high flammability i.e. (i) mostly hydrocarbons and organic polymers from nearby industries in the vicinity of Bellandur lake and (ii) phosphorous from detergents. High wind coupled with high intensity of rainfall leads to upwelling of sediments with the churning of water as it travels from higher elevation to lower elevation forming froth due to phosphorous. Discharge of untreated effluents (rich in hydro carbon and phosphorous) with accidental fire (like throwing cigarettes, beedi) has led to the fire in the lake. Colour of the flame and subsequent analyses of black particles (burnt residues) confirms the source (long chain hydro carbons) Based on these studies of preponderance of phosphates in domestic wastewater, surface waters and sludge/sediments and the increasing enrichments of these urban surface waters with large quantum of nutrient loads from untreated wastewaters comprising of P inputs from detergents and human excrements, the following actions needs to be implemented

1. Immediate reduction, and eventual eradication of phosphates in detergents through appropriate policy and legislations;
2. Awareness among consumers to select washing products with the least amount of polluting ingredients;
3. prompt promulgation of regulations requiring appropriate labelling of detergent packages listing of the ingredients and information about use of detergents in soft and hard water.
4. Enacting legislations to regulate/remove p based ingredients in household laundry detergents, as almost all detergents brands available in market invariably constitutes bulk of p based ingredients,
5. Identification of P detergent manufacturing units and inventorisation of phosphates based products in these units. Together with this a national accounting of total P imports, distribution, manufacturing into various end products and disposal of these commodities encompassing all sectors has to be documented.
6. More research and development on fate of P based ingredients in aquatic systems, from various sectors (Agricultural, Municipal etc.) has to be undertaken.
7. Incorporating mandates for nutrient (N and P) removal and recovery to the existing wastewater treatment systems that only focuses on BOD/COD and TSS removal as a criterion for disposal of water into streams and other surface water bodies.
8. Seeking participation from the local communities in surface and ground water quality monitoring and management and strictly applying the “polluter pays principle” to the rapidly declining surface waters would ensure conservation and protection of the fresh water resources.
